On-line construction of a small automaton for a finite set of words

Maxime Chrochemore and Laura Giambruno

Institut Gaspard-Monge, Université Paris-Est Dipartimento di Matematica e Applicazioni, Università di Palermo, Palermo

August 31,2009

Design a "light" algorithm for the on-line construction of a small automaton recognising a finite set of words in linear time.

- ▶ Finite sets of words *X* on a finite alphabet *A*.
- ▶ the *length n* of *X* is the sum of the lengths of the words in *X*:

$$n = \sum_{i=1}^{m} |u_i|$$

Design a "light" algorithm for the on-line construction of a small automaton recognising a finite set of words in linear time.

- ► Finite sets of words *X* on a finite alphabet *A*.
- ▶ the *length n* of *X* is the sum of the lengths of the words in *X*:

$$n = \sum_{i=1}^{m} |u_i|$$

- Interesting for parsing natural text and for motif detection
- Used in many software like the intensively used BLAST
- Dictionaries used for natural languages can contain a large number of words.

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ●

Automata for finite sets of words: classical construction

- ► represent a list *X* by a trie
- minimise the trie to get the minimal automaton of the finite set of words of the list.

This solution requires a large memory space to store the temporary large data structure.

Automata for finite sets of words: classical construction

- ► represent a list *X* by a trie
- minimise the trie to get the minimal automaton of the finite set of words of the list.

This solution requires a large memory space to store the temporary large data structure.

- pseudo-minimisation algorithm by Revuz (1991)
- algorithm that constructs a minimal automaton for an ordered set of strings by Daciuk et al. (2000)

- semi-incremental algorithm for constructing minimal acyclic deterministic automata by Watson (2003)
- efficient algorithm to insert a word in a minimal acyclic by Sgarbas et al. (2003)

Intermediate solution

to build a rather small automaton with a light algorithm processing the list of words on- line in linear time on the length of the list.

► The aim is not to get the corresponding minimal automaton but just a small enough structure.

◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ ○ ●

► However, the minimal automaton can be later obtained with Revuz linear algorithm (1992).

Intermediate solution

to build a rather small automaton with a light algorithm processing the list of words on- line in linear time on the length of the list.

The aim is not to get the corresponding minimal automaton but just a small enough structure.

► However, the minimal automaton can be later obtained with Revuz linear algorithm (1992).

- ► the automaton can possibly be built on demand
- ▶ our solution avoids building a temporary large trie

Advantages of our algorithm

Simplicity, linear time algorithm, on-line construction and the fact that resulting automaton seems to be really close to minimal.

うして 山口 マイビット ビー うくの

- the automaton can possibly be built on demand
- ▶ our solution avoids building a temporary large trie

Advantages of our algorithm

Simplicity, linear time algorithm, on-line construction and the fact that resulting automaton seems to be really close to minimal.

Let *A* be a finite alphabet. For $X = (x_0, ..., x_m)$ list of words, |X| denotes the cardinality of *X*.

◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ ○ ●

A deterministic automaton over A is $\mathcal{A} = (Q, i, T, \delta)$, where

- ► *Q* is a finite set of *states*
- ► *i* is the initial state
- $T \subseteq Q$ is the subset of *final* states
- $\delta: Q \times A \longrightarrow Q$ is the *transition function*

Let < be an order on the elements in *A* Lexicographic order $<_{lex}$: for u, v in A^* we have that $u <_{lex} v$ if, and only if

- u is a prefix of v
- u and v have a prefix u_0 in common, $u = u_0 a u_1$, $v = u_0 b v_1$ and $a <_{lex} b$

Hypothesis

We consider a list of words X in A^* such that the list obtained reversing each word in X is sorted according to the lexicographic order.

Example

X = (aaa, ba, aab) satisfies our hypothesis.

Idea of the construction

- ► We define inductively a sequence of |X| + 1 automata A⁰_X,...,A^{|X|}_X.
- For each k, the automaton \mathcal{A}_X^k recognises the language $\{x_0, \ldots, x_k\}$.
- In particular \mathcal{A}_X^m will recognises X

For each k, there is a unique final state q_{fin} without any outgoing transitions.

Idea

Define \mathcal{A}_X^0 $\mathcal{A}_X^{k-1} \longrightarrow \mathcal{A}_X^k$ by adding a path in \mathcal{A}_X^{k-1} in order to add x_k to $L(\mathcal{A}_X^{k-1})$.

Let \mathcal{A}_X^k with set of states Q_k and

$$H, Deg^{-}(j), PF: Q_k \longrightarrow N$$

such that for $j \in Q_k$:

- *Height*: H(j) is the maximal length of paths from *j* to a final state.
- *Indegree*: $Deg^{-}(j)$ is the number of edges ending at *j*.
- ► Paths toward final states: for j ≠ q_{fin}, PF(j) is the number of paths starting at j and ending at final states and PF(q_{fin}) = 1.

Example

うしつ 川 ふ う く 川 マ く 見 マ く 日 マ

- ► H(0) = 3, H(1) = 2, H(2) = 1, H(3) = 0
- ▶ $Deg^{-}(0) = 0, Deg^{-}(1) = Deg^{-}(3) = 1, Deg^{-}(2) = 2$
- ▶ PF(0) = 2, PF(1) = PF(2) = PF(3) = 1

Let \mathcal{A}_X^k with set of states Q_k and

$$H, Deg^{-}(j), PF: Q_k \longrightarrow N$$

such that for $j \in Q_k$:

- *Height*: H(j) is the maximal length of paths from *j* to a final state.
- *Indegree*: $Deg^{-}(j)$ is the number of edges ending at *j*.
- ► Paths toward final states: for j ≠ q_{fin}, PF(j) is the number of paths starting at j and ending at final states and PF(q_{fin}) = 1.

Example

うしつ 川 ふ う く 川 マ く 見 マ く 日 マ

- H(0) = 3, H(1) = 2, H(2) = 1, H(3) = 0
- ▶ $Deg^{-}(0) = 0$, $Deg^{-}(1) = Deg^{-}(3) = 1$, $Deg^{-}(2) = 2$

▶ PF(0) = 2, PF(1) = PF(2) = PF(3) = 1

Let \mathcal{A}_X^k with set of states Q_k and

$$H, Deg^{-}(j), PF: Q_k \longrightarrow N$$

such that for $j \in Q_k$:

- *Height*: H(j) is the maximal length of paths from *j* to a final state.
- *Indegree*: $Deg^{-}(j)$ is the number of edges ending at *j*.
- ► Paths toward final states: for j ≠ q_{fin}, PF(j) is the number of paths starting at j and ending at final states and PF(q_{fin}) = 1.

Example

うしつ 川 ふ う く 川 マ く 見 マ く 日 マ

- ► H(0) = 3, H(1) = 2, H(2) = 1, H(3) = 0
- ► $Deg^{-}(0) = 0$, $Deg^{-}(1) = Deg^{-}(3) = 1$, $Deg^{-}(2) = 2$
- ► PF(0) = 2, PF(1) = PF(2) = PF(3) = 1

Construction of \mathcal{A}_X^0

Let $\mathcal{A}_X^0 = (Q_0, i_0, T_0, \delta_0)$ be a path with label x_0 from $i_0 = 0$ to $|x_0| = q_{fin}$ unique final state.

- The elements in Q_0 are integers
- $i_0 = 0$ and $T_0 = \{|x_0|\}$
- $\blacktriangleright L(\mathcal{A}^0_X) = \{x_0\}$

Example

$$X = (aaa, ba, aab)$$

Construction of \mathcal{A}_X^k from \mathcal{A}_X^{k-1}

$$\mathcal{A}_X^{k-1} = (Q_{k-1}, i_{k-1}, T_{k-1}, \delta_{k-1}) \longrightarrow \mathcal{A}_X^k = (Q_k, i_k, T_k, \delta_k)$$

- $i_k = 0$
- $u \longrightarrow$ the longest prefix in common between x_k and the elements in $\{x_0, \ldots, x_{k-1}\}$.
- ▶ *s* \longrightarrow the longest suffix in common between x_k and x_{k-1} .
- ▶ if *s* and *u* overlap we consider as *s* the suffix of x_k of length $|x_k| |u| + 1$.
- $x_k = uws$, with $w \neq \varepsilon$.

For X = (aaa, ba, aab) and for $x_2 = aab, u$ is aa and s is ε .

うして 山口 マイビット ビー うくの

Construction of \mathcal{A}_X^k from \mathcal{A}_X^{k-1}

$$\mathcal{A}_X^{k-1} = (Q_{k-1}, i_{k-1}, T_{k-1}, \delta_{k-1}) \longrightarrow \mathcal{A}_X^k = (Q_k, i_k, T_k, \delta_k)$$

- $\blacktriangleright i_k = 0$
- $u \longrightarrow$ the longest prefix in common between x_k and the elements in $\{x_0, \ldots, x_{k-1}\}$.
- ▶ *s* \longrightarrow the longest suffix in common between x_k and x_{k-1} .
- ► if *s* and *u* overlap we consider as *s* the suffix of x_k of length $|x_k| |u| + 1$.
- $x_k = uws$, with $w \neq \varepsilon$.

For X = (aaa, ba, aab) and for $x_2 = aab, u$ is aa and s is ε .

うして 山口 マイビット ビー うくの

 $p \longrightarrow$ the end state of the path in \mathcal{A}_X^{k-1} starting at 0 with label u $q \longrightarrow$ the state along the path from 0 with label x_{k-1} for which the sub-path from q to q_{fin} has label s

◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ ○ ●

Example

For $x_2 = aab$, *p* is the state 2 and *q* is the state 3.

Construction of \mathcal{A}_X^k from \mathcal{A}_X^{k-1}

General idea

The general idea of the construction of \mathcal{A}_X^k from \mathcal{A}_X^{k-1} would be to add a path from *p* to *q* with label *w*.

The automaton \mathcal{A}_X^1 is obtained from \mathcal{A}_X^0 by adding the edge (0, b, 2).

Attention!

In general we cannot add a path from p to q with label w since we would add words other than x_k . We have to do some controls.

Example

$$X = (aaa, ba, aab)$$

Figure: \mathcal{A}_X^1 , the incorrect construction of \mathcal{A}_X^2

Since $Deg^{-}(2) > 1$, adding the edge (2, b, 3) leads to an automaton accepting {aaa, ba, aab, bb}.

Indegree control

Before adding a path from *p* to *q*, we have to do a transformation of the automaton $\mathcal{A}_X^1 \longrightarrow \mathcal{B}_X^1$.

Example

X = (aaa, ba, aab)

 \mathcal{B}_X^1 is obtained from \mathcal{A}_X^1 by doing a copy of the path from 0 to 4 with label aa.

Example

X = (aaa, ba, aab)

 \mathcal{A}_X^2 is obtained by adding the edge (4, b, 3).

If, in \mathcal{A}_X^{k-1} , in the path from 0 with label *u* there are states *r* with $Deg^-(r) > 1$ then

 $\mathcal{A}_X^{k-1} \longrightarrow \mathcal{B}_X^{k-1}$

In this case:

- \mathcal{B}_X^{k-1} is obtained by doing a copy of the path from *r* to *p*
- \mathcal{B}_X^{k-1} is equivalent to \mathcal{A}_X^{k-1}
- $p \longrightarrow$ the end state of the path from 0 with label u in \mathcal{B}_X^{k-1} .

うして 山口 マイビット ビー うくの

► If x_k is the prefix of a word in {x₀,..., x_{k-1}} then we add p to the set of final states.

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ · □□ · ○ へ ()

• Otherwise we proceed with the following controls.

Example

X = (aaa, ba, aab, abb)

Figure: \mathcal{A}_X^2 and the incorrect construction of \mathcal{A}_X^3

・ロト ・ 何 ト ・ ヨ ト ・ ヨ

We have PF(4) = 2. Adding the edge (1, b, 4) to \mathcal{A}_X^2 leads to an automaton accepting {aaa, ba, aab, abb, aba}.

Path toward final states control

Example X = (aaa, ba, aab, abb)

 \mathcal{A}_X^3 is obtained by adding the path from 1 to 3 with label bb. The state 3 is the first state q' in the path from 4 = q to 3 with PF[q'] = 1

If PF(q) > 1

- ► consider in the path from q to q_{fin} with label s the first state q' such that PF[q'] = 1, if it exists.
- redefine q as q'
- ▶ redefine *w* and *s*
- ▶ If there is no q' with PF[q'] = 1, redefine q as q_{fin} and w as ws.

Figure: \mathcal{A}_X^0 and the incorrect construction of \mathcal{A}_X^1

We have that p = 1 = q have the same *H* Adding the edge (2, b, 1) in \mathcal{A}_X^0 would lead to an automaton accepting the infinite language {aba, a (bb)*a}.

Example

X = (aba, abbba)

 \mathcal{A}_X^1 is obtained by adding the path from 2 to 3 with label bba. The state 3 is the first state q' in the path from 2 to 3 with H[p] > H[q']

 $\mathrm{If}\, H[p] \leq H[q]$

► consider in the path from q to q_{fin} with label s the first state q' such that H[p] > H[q].

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - のへぐ

- redefine q as q'
- ▶ redefine *w* and *s*

Control on q_{fin}

Figure: Incorrect construction of \mathcal{A}_X^4 and the right construction of \mathcal{A}_X^4

Adding an edge from p = 3 to $q_{fin} = 3$ would lead to infinitely many words to the language recognised by the automaton.

If there exists a word in $\{x_0, \ldots, x_{k-1}\}$ that is a prefix of x_k then

• if $p \neq q_{fin}$ we add p to the set of final states and the construction is terminated.

In all cases we add a path from p to q with label w.

Theorem

For each $k \in \{0, ..., m\}$, the language recognised by the automaton \mathcal{A}_X^k is $L(\mathcal{A}_X^k) = \{x_0, ..., x_k\}$.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - のへぐ

Theorem

Let $X = (x_0, ..., x_m)$ be a list of words in A^* ordered by right-to-left lexicographic order and let $\sum_{i=0,m} |x_i| = n$. There is an algorithm for the construction of the automaton \mathcal{A}_X^m recognising X in $\mathcal{O}(n)$.

うして 山口 マイビット ビー うくの

CONSTRUCTION-
$$\mathcal{A}_X(X)$$

1. $(\mathcal{A}, R) \leftarrow$ CONSTRUCTION- \mathcal{A}_X^0 $(X[0])$
2. for $k \leftarrow 1$ to $|X| - 1$ do
3. $(\mathcal{A}, R) \leftarrow$ Add-word $(\mathcal{A}, X[k], X[k-1], R)$
4. Return \mathcal{A}

Non minimality of the automaton

 \mathcal{A}_X^3 is not minimal since the states 2 and 4 are equivalent.

Example X = (aaa, ba, aab, bb)

Figure: \mathcal{A}_X^1 , the incorrect construction of \mathcal{A}_X^2

In this example bb is also in X. In this case the indegree control is not necessary.

- Let y in A^* and S(y) be the set of suffixes of y.
- ► *S*(*y*) sorted by decreasing order on the lengths of the elements in *S*(*y*).

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - のへぐ

- ► denote by A_y the automaton A_{S(y)} and by M_y the minimal automaton of S(y).
- $\mathcal{A} \longrightarrow \# \mathcal{A}$ the number of states of \mathcal{A} .

We consider the ratio $D(y) = \frac{\sharp A_y}{\sharp M_y}$.

We have done experiments on the set of suffixes of a given word.

• $D_n^{max} \longrightarrow$ the greatest of D(y) with y of length n.

n	D_n^{max}
10	1.83
15	2.41
20	3.04

- $D_n^{max} \le 4$ for words y with $|y| \le 20$.
- Bad cases linked with words powers of a short one with great exponent

- $D_n \longrightarrow$ the greatest ratio among the D(y)
- In each column we have \mathcal{D}_n for a set of generated words which either are not powers of the same word or are powers of a word with an exponent less than a fixed number.

п	exp < 3	exp < 2	exp < 1
10	1.75	1.66	1.54
20	2.22	2.16	2.42
30	2.16	2.22	2.24
50	1.96	1.85	2.60
100	1.60	1.71	1.79

The experimental results are good in general even if they do not show clearly our conjecture.

- $D_n \longrightarrow$ the greatest ratio among the D(y)
- In each column we have \mathcal{D}_n for a set of generated words which either are not powers of the same word or are powers of a word with an exponent less than a fixed number.

n	exp < 3	exp < 2	exp < 1
10	1.75	1.66	1.54
20	2.22	2.16	2.42
30	2.16	2.22	2.24
50	1.96	1.85	2.60
100	1.60	1.71	1.79

The experimental results are good in general even if they do not show clearly our conjecture.

PF control and Height control are not necessary in this case.

Lemma

Let y in A^* and y_k in S(y) such that y_k is not a prefix of a word in $\{y_0, \ldots, y_{k-1}\}$. Then we have that PF(q) = 1.

Lemma

Let y in A^* and y_k in S(y) such that y_k is not a prefix of a word in $\{y_0, \ldots, y_{k-1}\}$. Then we have that H(p) > H(q).

Set of suffixes of a given word: modified construction

- ► We propose a modified Indegree control in order to avoid equivalent states as in the example.
- ▶ We expect that an improved version of the algorithm actually builds the (minimal) suffix automaton of *y*.

► Find a general upper bound for ratios D

Does there exist an on-line construction for the minimal automaton accepting a finite set of words that runs in linear time on each word being inserted in the automaton?
